

STAT525 HOMEWORK#4

1. Consider the following data set that describes the relationship between “velocity” of an enzymatic reaction (V) and the substrate concentration (C).

Concentration	Velocity
0.02	76
0.02	47
0.06	97
0.06	107
0.11	123
0.11	139
0.22	159
0.22	152
0.56	191
0.56	201
1.10	207
1.10	200

A common model used to describe the relationship between “velocity” and concentration is the Michaelis-Menten model

$$V = \frac{\theta_1 C}{\theta_2 + C}$$

where θ_1 is the maximum velocity of the reaction and θ_2 describes how quickly (in terms of increasing concentration) the reaction will reach maximum velocity. With this model, $1/V$ can be written as a linear model with explanatory variable $1/C$.

$$\frac{1}{V} = \frac{1}{\theta_1} + \frac{\theta_2}{\theta_1} \left(\frac{1}{C} \right) = \beta_0 + \beta_1 \left(\frac{1}{C} \right)$$

You are asked to investigate whether this linear transformation results in a good or poor fit by doing the following steps:

- a. Generate a scatterplot of V vs C . Comment on the shape.
- b. Define new variables for $1/V$ and $1/C$ in SAS and generate a scatterplot. These new variables can be defined as follows:

```
DATA NEW;
  INPUT c v;
  vinv = 1/v;
  cinv = 1/c;
  CARDS;
  [PUT DATA HERE]
;
```

Does the fit appear linear? Does there appear to be any violation of assumptions?

- c. Is the distribution of $1/C$ different than C ? Are there any points that may be more influential in determining the fit?
- d. Determine the least squares regression line for $1/V$ vs $1/C$. Save the residuals and predicted values. Does the residual plot suggest any problems?
- e. Convert this regression line back into the original nonlinear model and plot the predicted curve on a scatterplot of V vs C . Comment on the fit. To generate the predicted curve, simply take the predicted values from the regression model and “re-inverse” them. For example, consider new1 to be the data set containing the residuals and predicted values.

```
DATA new1;
    SET new1;
    pred1 = 1/pred;

    SYMBOL1 V=CIRCLE I=NONE C=BLACK;
    SYMBOL2 V=PLUS I=SM5 C=BLACK;
    PROC GLOT;
        PLOT v*c=1 pred1*c=2 / OVERLAY;
    RUN;
```

2. KNNL Problem 4.12. This can be done in SAS or by hand. To fit a model with no intercept in SAS, you need to add the NOINT option on MODEL statement line.
3. KNNL Problem 4.21
4. KNNL Problem 4.25 (STAT Majors)
5. KNNL Problem 6.2
6. (SAS Exercise) Use the **brand preference** data described in KNNL Problem 6.5. Run the linear regression with moisture and sweetness of the product as the explanatory variables and degree of liking as the response variable.
 - a. Summarize the regression results by giving the fitted regression equation, the value of R^2 .
 - b. State the results of the significance test for the null hypothesis that the two regression coefficients for the explanatory variables are *all* zero (give null and alternative hypotheses, test statistic with degrees of freedom, p -value, and a brief conclusion in words).
 - c. Describe the results of the hypothesis tests for the individual regression coefficients (give null and alternative hypotheses, test statistic with degrees of freedom, p -value, and a brief conclusion in words).
 - d. Give separate 95% confidence intervals for the regression coefficients of sweetness and moisture. What is the relationship between these confidence intervals and the above hypothesis results?

1. Consider the following data set that describes the relationship between “velocity” of an enzymatic reaction (V) and the substrate concentration (C).

```
2 data enzyme;  
3     input concentration velocity;  
4     datalines;  
5 0.02 76  
6 0.02 47  
7 0.06 97  
8 0.06 107  
9 0.11 123  
10 0.11 139  
11 0.22 159  
12 0.22 152  
13 0.56 191  
14 0.56 201  
15 1.10 207  
16 1.10 200  
17 ;  
18 run;
```

- a. Generate a scatterplot of V vs C . Comment on the shape.

```
21 proc sgplot data=enzyme;  
22     scatter x=concentration y=velocity;  
23     xaxis label="Concentration (C)";  
24     yaxis label="Velocity (V)";  
25     title "Scatterplot of Velocity vs. Concentration";  
26 run;
```

The relationship is nonlinear:

- $\uparrow$ rapidly at low concentrations and begins to plateau as concentration $\uparrow$, hence consistent with the Michaelis-Menten kinetics.

- Michaelis-Menten kinetics: reaction velocity $\uparrow$ quickly at first but approaches a maximum velocity (V_i) as substrate concentration $\uparrow$.

- shape is concave down (decelerating increase), $\uparrow C$, $\downarrow$ in gains of V .

- Linear Model would not be appropriate, should opt for nonlinear / transformed model.

b. Define new variables for $1/V$ and $1/C$ in SAS and generate a scatterplot. These new variables can be defined as follows:

Does the fit appear linear? Does there appear to be any violation of assumptions?

```
29 data enzyme2;
30     set enzyme;
31     vinv = 1 / velocity;
32     cinv = 1 / concentration;
33 run;
34
35 proc sgplot data=enzyme2;
36     scatter x=cinv y=vinv;
37     xaxis label="1 / Concentration (1/C)";
38     yaxis label="1 / Velocity (1/V)";
39     title "Lineweaver-Burk Plot (1/V vs 1/C)";
40 run;
```

Yes. Transformed data appear to form a rough linear trend, especially for mid to high concentrations.

Violations? :

- There are 2 points on the far right that appear far from the cluster, coming from the lowest concentration, C , but largest $1/C$.

- These points can exert $\uparrow$ leverage and may influence the regression line disproportionately.

- Suggesting a possible violation of equal variance (heteroscedasticity) and potential influential outliers.

$1/C=50$

c. Is the distribution of $1/C$ different than C ? Are there any points that may be more influential in determining the fit?

```
50 proc univariate data=enzyme;
51     var concentration;
52     histogram;
53     qqplot;
54     title "Distribution of C (Concentration)";
55 run;
56
57 proc univariate data=enzyme2;
58     var cinv;
59     histogram;
60     qqplot;
61     title "Distribution of 1/C (cinv)";
62 run;
```

Yes. Distribution for $1/C$ is much more skewed and stretched than the Distribution for C .

- The smallest C (especially $C=0.02$) result in very large $1/C$, which may act as influential points and could potentially distort the linear regression fit.

d. Determine the least squares regression line for $1/V$ vs $1/C$. Save the residuals and predicted values. Does the residual plot suggest any problems?

```

65 proc reg data=enzyme2 outest=est;
66     model vinv = cinv;
67     output out=reg_out p=vinv_pred r=resid;
68     title "Regression: 1/V vs 1/C";
69 run;
70 quit;
71
72 /* Residual plot */
73 proc sgplot data=reg_out;
74     scatter x=cinvs y=resid;
75     refline 0 / axis=y lineattrs=(color=red);
76     xaxis label="1 / Concentration (1/C)";
77     yaxis label="Residuals";
78     title "Residual Plot from Lineweaver-Burk Regression";
79 run;

```

Regression: 1/V vs 1/C

The REG Procedure
Model: MODEL1
Dependent Variable: vinv

Number of Observations Read	12
Number of Observations Used	12

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	0.00021232	0.00021232	59.30	<.0001
Error	10	0.00003581	0.00000358		
Corrected Total	11	0.00024813			

Root MSE	0.00189	R-Square	0.8557
Dependent Mean	0.00853	Adj R-Sq	0.8413
Coeff Var	22.19144		

Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	0.00511	0.00070400	7.25	<.0001
cinvs	1	0.00024722	0.00003210	7.70	<.0001

Fitted Regression Line:

$$\hat{1/V} = 0.00511 + 0.00024722 \cdot (1/C)$$

problem!

- Points do not scatter randomly around line of fit.
- $e^2 \uparrow$ in conical fashion.

- Model explains a large proportion of the variation in $1/V$ ($R^2 = 0.8577$)
- e^2 plot shows 2 extreme values with large residuals, likely due to influence from very small C 's (e.g. $C = 0.02$).
- These extreme values may impact the stability of the model and violate equal variance (heteroscedasticity).

- e. Convert this regression line back into the original nonlinear model and plot the predicted curve on a scatterplot of V vs C . Comment on the fit. To generate the predicted curve, simply take the predicted values from the regression model and "re-inverse" them. For example, consider new1 to be the data set containing the residuals and predicted values.

```

82 data reg_out2;
83     set reg_out;
84     pred_velocity = 1 / vinv_pred;
85 run;
86
87 proc sgplot data=reg_out2;
88     scatter x=concentration y=velocity / markerattrs=(symbol=circlefilled);
89     series x=concentration y=pred_velocity / lineattrs=(color=red thickness=2);
90     xaxis label="Concentration (C)";
91     yaxis label="Velocity (V)";
92     title "Original Data with Fitted Michaelis-Menten Curve";
93 run;

```

• Fitted curve from the Michaelis-Menten model aligns well with the original V , especially at mid-to-high C 's.

• The shape of the fitted line captures the expected saturation effect of enzyme kinetics.

• Minor deviations are seen at ↓ C 's, but overall the model provides a good fit and represent the underlying relationship well.

2. KNNL Problem 4.12. This can be done in SAS or by hand. To fit a model with no intercept in SAS, you need to add the NOINT option on MODEL statement line.

4.12. Typographical errors. Shown below are the number of galleys for a manuscript (X) and the total dollar cost of correcting typographical errors (Y) in a random sample of recent orders handled by a firm specializing in technical manuscripts. Since Y involves variable costs only, an analyst wished to determine whether regression-through-the-origin model (4.10) is appropriate for studying the relation between the two variables.

i :	1	2	3	4	5	6	7	8	9	10	11	12
X_i :	7	12	10	10	14	25	30	25	18	10	4	6
Y_i :	128	213	191	178	250	446	540	457	324	177	75	107

- a. Fit regression model (4.10) and state the estimated regression function.

```

100 data typos;
101     input x y;
102     datalines;
103 7 128
104 12 213
105 10 191
106 10 178
107 14 250
108 25 446
109 30 540
110 25 457
111 18 324
112 10 177
113 4 75
114 6 107
115 ;
116 run;
117
118 /* Fit regression through the origin */
119 proc reg data=typos;
120     model y = x / noint;
121     title "Regression Through the Origin: Typo Cost vs. Galleys";
122 run;

```

Fitted Regression Line: $\hat{Y} = 18.02830 \cdot X$

Regression Through the Origin: Typo Cost vs. Galleys

The REG Procedure
Model: MODEL1
Dependent Variable: y

Number of Observations Read	12
Number of Observations Used	12

Note: No intercept in model. R-Square is redefined.

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	1044939	1044939	51446.2	<.0001
Error	11	223.42426	20.31130		
Uncorrected Total	12	1045162			

Root MSE	4.50681	R-Square	0.9998
Dependent Mean	257.16667	Adj R-Sq	0.9998
Coeff Var	1.75248		

Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
x	1	18.02830	0.07948	226.82	<.0001

- b. Plot the estimated regression function and the data. Does a linear regression function through the origin appear to provide a good fit here? Comment.

```

125 /* (2b) Scatterplot with fitted regression line through origin */
126 proc sgplot data=typos;
127   scatter x=x y=y / markerattrs=(symbol=circlefilled);
128   reg x=x y=y / noint lineattrs=(color=red thickness=2);
129   xaxis label="Number of Galleys (X)";
130   yaxis label="Typo Correction Cost (Y)";
131   title "Regression Through the Origin: Cost vs. Galleys";
132 run;

```

- The fit plot shows the regression-through-the-origin model provides an excellent fit to the data.
- Observed points align closely with fitted line, with very narrow CI and PI.
- The $\uparrow\uparrow\uparrow R^2 (0.9998)$, with visual evidence, confirms linear model without intercept is highly appropriate for modeling # of galley v.s. typo #.

- c. In estimating costs of handling prospective orders, management has used a standard of \$17.50 per galley for the cost of correcting typographical errors. Test whether or not this standard should be revised; use $\alpha = .02$. State the alternatives, decision rule, and conclusion.

$$H_0: \beta_1 = 17.50 \text{ (standard)}$$

$$H_A: \beta_1 \neq 17.50 \text{ (non-standard)}$$

$$t^* = \frac{\hat{\beta}_1 - H_0}{SE} = \frac{18.02830 - 17.50}{0.07948} = 6.64696 \ggg 2.718$$

$$t_{\alpha/2, df} = t_{0.01, 11} = 2.718$$

- Reject H_0 . At $\alpha = 0.02$, $t^* > t$

- There is sufficient evidence to conclude true cost /galley $\neq$ \$17.50, so standard should be revised.

- d. Obtain a prediction interval for the correction cost on a forthcoming job involving 10 galleys. Use a confidence coefficient of 98 percent.

```

135 data predict;
136   input x;
137   datalines;
138 10
139 ;
140 run;
141
142 data all;
143   set typos predict;
144 run;
145
146 proc reg data=all;
147   model y = x / noint clm cli alpha=0.02; /* 98% confidence (a.

3. KNNL Problem 4.21

4.21. When the predictor variable is so coded that $\bar{X} = 0$ and the normal error regression model (2.1) applies, are b_0 and b_1 independent? Are the joint confidence intervals for β_0 and β_1 then independent?

Yes. $\hat{\beta}_0$ and $\hat{\beta}_1$ are independent when $\bar{X} = 0$, and normal assumption holds.

• Under standard simple linear regression model, the covariance $\hat{\beta}_0$ and $\hat{\beta}_1$: $\text{Cov}(\hat{\beta}_0, \hat{\beta}_1) = \frac{-\bar{X} \cdot \sigma^2}{\sum x_i^2}$
So if $\bar{X} = 0$, $\text{Cov}(\hat{\beta}_0, \hat{\beta}_1) = 0$.

However, the joint CI for $\hat{\beta}_0, \hat{\beta}_1$ are not independent.

• A joint CI accounts for simultaneous variability, and doesn't break into 2 independent intervals, even if $\hat{\beta}_0$ and $\hat{\beta}_1$ are uncorrelated.
↓
(elliptical region under multivariate t-distribution)

4. KNNL Problem 4.25 (STAT Majors) (Skipped)

4.25. Derive the formula for $s^2\{\hat{Y}_h\}$ given in Table 4.1 for linear regression through the origin.

Step 1: Variance of the prediction

Model:

$$\text{Var}(\hat{Y}_h) = \text{Var}(\hat{\beta}_1 X_h) = X_h^2 \cdot \text{Var}(\hat{\beta}_1)$$

We assume the linear regression through the origin:

$$Y_i = \beta_1 X_i + \varepsilon_i, \quad \varepsilon_i \sim \text{iid } N(0, \sigma^2)$$

Step 2: Variance of $\hat{\beta}_1$ in regression through the origin:

Let:

- $\hat{\beta}_1 = \frac{\sum X_i Y_i}{\sum X_i^2}$
- $\hat{Y}_h = \hat{\beta}_1 X_h$ be the predicted value at point X_h

$$\text{Var}(\hat{\beta}_1) = \frac{\sigma^2}{\sum X_i^2}$$

So:

$$\text{Var}(\hat{Y}_h) = X_h^2 \cdot \frac{\sigma^2}{\sum X_i^2}$$

Final Answer:

$$s^2\{\hat{Y}_h\} = s^2 \cdot \frac{X_h^2}{\sum X_i^2}$$

Step 3: Estimate σ^2 using the MSE:

$$s^2 = \frac{\text{SSE}}{n - 1}$$

5. KNNL Problem 6.2

6.2. Set up the $\mathbf{X}$ matrix and $\boldsymbol{\beta}$ vector for each of the following regression models (assume $i = 1, \dots, 5$):

a. $Y_i = \beta_1 X_{i1} + \beta_2 X_{i2} + \beta_3 X_{i1}^2 + \varepsilon_i$

b. $\sqrt{Y_i} = \beta_0 + \beta_1 X_{i1} + \beta_2 \log_{10} X_{i2} + \varepsilon_i$

a) $Y_i = \beta_1 X_{i1} + \beta_2 X_{i2} + \beta_3 X_{i1}^2 + \varepsilon_i$

b) $\sqrt{Y_i} = \beta_0 + \beta_1 X_{i1} + \beta_2 \log_{10} X_{i2} + \varepsilon_i$

$$\mathbf{X} = \begin{bmatrix} X_{11} & X_{12} & X_{11}^2 \\ X_{21} & X_{22} & X_{21}^2 \\ X_{31} & X_{32} & X_{31}^2 \\ X_{41} & X_{42} & X_{41}^2 \\ X_{51} & X_{52} & X_{51}^2 \end{bmatrix} \quad \boldsymbol{\beta} = \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix}$$

$$\mathbf{X} = \begin{bmatrix} 1 & X_{11} & \log_{10}(X_{12}) \\ 1 & X_{21} & \log_{10}(X_{22}) \\ 1 & X_{31} & \log_{10}(X_{32}) \\ 1 & X_{41} & \log_{10}(X_{42}) \\ 1 & X_{51} & \log_{10}(X_{52}) \end{bmatrix} \quad \boldsymbol{\beta} = \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \end{bmatrix} \quad \mathbf{Y} = \begin{bmatrix} \sqrt{Y_1} \\ \sqrt{Y_2} \\ \sqrt{Y_3} \\ \sqrt{Y_4} \\ \sqrt{Y_5} \end{bmatrix}$$

6. (SAS Exercise) Use the **brand preference** data described in KNNL Problem 6.5. Run the linear regression with moisture and sweetness of the product as the explanatory variables and degree of liking as the response variable.

6.5. **Brand preference.** In a small-scale experimental study of the relation between degree of brand liking (Y) and moisture content (X_1) and sweetness (X_2) of the product, the following results were obtained from the experiment based on a completely randomized design (data are coded):

i :	1	2	3	...	14	15	16
X_{i1} :	4	4	4	...	10	10	10
X_{i2} :	2	4	2	..	4	2	4
Y_i :	64	73	61	...	95	94	100

- a. Summarize the regression results by giving the fitted regression equation, the value of R^2 .

```

1 data brand_pref;
2   input liking moisture sweetness;
3   datalines;
4 64 4 2
5 73 4 4
6 61 4 2
7 76 4 4
8 72 6 2
9 80 6 4
10 71 6 2
11 83 6 4
12 83 8 2
13 89 8 4
14 86 8 2
15 93 8 4
16 88 10 2
17 95 10 4
18 94 10 2
19 100 10 4
20 ;
21 run;
22
23 proc reg data=brand_pref;
24   model liking = moisture sweetness;
25   title "Regression of Liking on Moisture and Sweetness";
26 run;

```

Regression of Liking on Moisture and Sweetness

The REG Procedure

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	37.65000	2.99610	12.57	<.0001
moisture	1	4.42500	0.30112	14.70	<.0001
sweetness	1	4.37500	0.67332	6.50	<.0001

Fitted Regression Line: $\widehat{\text{liking}} = 37.6500 + 4.42500 \cdot \text{Moisture} + 4.37500 \cdot \text{Sweetness}$

$$R^2 = 0.9521$$

• 95% of variation in degree of liking is explained by Moisture and Sweetness.

- b. State the results of the significance test for the null hypothesis that the two regression coefficients for the explanatory variables are *all* zero (give null and alternative hypotheses, test statistic with degrees of freedom, p -value, and a brief conclusion in words).

$$H_0: \beta_1 = \beta_2 = 0$$

$$H_A: \text{At least one } \beta_1 \text{ or } \beta_2 \neq 0$$

(Results from 6a):

$$F = 129.08$$

$$df_1 (\text{model}) = 2$$

$$df_2 (\text{error}) = 13$$

$$p\text{-value} < 0.0001$$

Reject H_0 at any α level.

→

• There is strong evidence that at least one β (Moisture or Sweetness) is significantly associated with degree of liking.

- c. Describe the results of the hypothesis tests for the individual regression coefficients (give null and alternative hypotheses, test statistic with degrees of freedom, p -value, and a brief conclusion in words).

Moisture

$$H_0: \beta_1 = 0$$

$$H_A: \beta_1 \neq 0$$

$$t^* = \frac{4.4250}{0.30112} = 14.70$$

$$df = 13$$

$$p\text{-value: } p < 0.0001$$

Reject H_0 . Moisture is significantly associated with degree of liking.

Sweetness

$$H_0: \beta_2 = 0$$

$$H_A: \beta_2 \neq 0$$

$$t^* = \frac{4.3750}{0.67332} = 6.50$$

$$df = 13$$

$$p\text{-value: } p < 0.0001$$

Reject H_0 . Sweetness is significantly associated with degree of liking.

Both Moisture or Sweetness have strong evidence of significantly associated with degree of liking.

- d. Give separate 95% confidence intervals for the regression coefficients of sweetness and moisture. What is the relationship between these confidence intervals and the above hypothesis results?

$$t_{0.025, 13} = 2.160$$

Moisture

(Results from 6a):

- Estimate: 4.4250
- SE: 0.30112
- df: 13

$$CI: 4.4250 \pm 2.160 \times 0.30112 = 4.4250 \pm 0.6504$$

$\Downarrow$

$$[3.7746, 5.0754] \text{ Moisture}$$

Sweetness

(Results from 6a):

- Estimate: 4.3750
- SE: 0.67332
- df: 13

$$CI: 4.3750 \pm 2.160 \times 0.67332 = 4.3750 \pm 1.4544$$

$\Downarrow$

$$[2.9206, 5.8294] \text{ Sweetness}$$

Both CI do not contain 0, matching conclusion in 6(c). $\rightarrow$ Rejected H_0 : All $\beta = 0$.

STAT525 HOMEWORK#4 Solution

1. Consider the given data set that describes the relationship between “velocity” of an enzymatic reaction (V) and the substrate concentration (C). You are asked to investigate whether this linear transformation results in a good or poor fit by doing the following steps:

- a. Generate a scatterplot of V vs C . Comment on the shape.

There is a nonlinear relationship between V and C . The spread in the observations at each level of C appears reasonably constant.

- b. Define new variables for $1/V$ and $1/C$ in SAS and generate a scatterplot. Does the fit appear linear? Does there appear to be any violation of assumptions?

While there does appear to be a linear relationship, the spread in the observations at each level of $1/C$ is no longer constant. Also, the small values of C are now extremely large values of $1/C$. Combine this with a larger variance and they may have a strong influence on the fit.

- c. Is the distribution of $1/C$ different than C ? Are there any points that may be more influential in determining the fit?

See description above. The linear regression may try to better fit those large values of $1/C$ at the expense of those observations with smaller $1/C$ values.

- d. Determine the least squares regression line for $1/V$ vs $1/C$. Save the residuals and predicted values. Does the residual plot suggest any problems?

Yes. The residual plot suggests nonconstant variance. One can also see that the residuals for small values of $1/C$ are either both positive or negative suggesting a poor fit.

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	0.00021232	0.00021232	59.30	<.0001
Error	10	0.00003581	0.00000358		
Corrected Total	11	0.00024813			

Root MSE	0.00189	R-Square	0.8557
Dependent Mean	0.00853	Adj R-Sq	0.8413
Coeff Var	22.19144		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	0.00511	0.00070400	7.25	<.0001
cinv	1	0.00024722	0.00003210	7.70	<.0001

- e. Convert this regression line back into the original nonlinear model and plot the predicted curve on a scatterplot of V vs C . Comment on the fit. To generate the predicted curve, simply take the predicted values from the regression model and “re-inverse” them. For example, consider new1 to be the data set containing the residuals and predicted values.

The curve appears to overpredict for low concentrations and underpredict at large values of C . Other estimation approaches, like nonlinear regression would be better to use here.

2. KNNL Problem 4.12. This can be done in SAS or by hand. To fit a model with no intercept in SAS, you need to add the NOINT option on MODEL statement line.

Using $b_1 = \sum XY / \sum X^2$ we get $\hat{Y} = 18.0283X$.

From the scatterplot, this appears to provide a very good fit. Management is interested in testing whether $H_0 : \beta_1 = 17.5$ vs the alternative $H_a : \beta_1 \neq 17.5$. In order to compute the test statistic, we need the $s(b_1)$. You can show that $MSE=20.3113$ and $s(b_1) = .07948$. Thus the test statistic is $t^* = (18.0283 - 17.5)/.07948 = 6.65$. Since $t(.99, 11) = 2.718$, we reject and conclude an adjustment needs to be made. Since $\hat{Y} = 18.0283X + e$, the standard error of a predicted value at $X = 10$ is $\sqrt{(10 \times .07948)^2 + 20.3113} = 4.576$. Thus the prediction interval is $180.283 \pm 2.718(4.576) = (167.845, 192.721)$.

3. KNNL Problem 4.21

The covariance matrix of $\mathbf{b}$ is $(X'X)^{-1} \sigma^2$. Since $\bar{X}$ is 0, the off-diagonal elements of this matrix will be zero. The parameter estimates are uncorellated. Because $\mathbf{b}$ is bivariate normal this implies the estimates are independent. Independence of the confidence interval implies that there is no correlation between the lower endpoints. If the variance were known

so the amount added and subtracted from the mean were constant, then the intervals would be independent. In this case, the variance is estimated from the data so there is a slight amount of correlation.

4. KNNL Problem 4.25

In this case $\hat{Y}_h = b_1 X_h$ so the variance will be $X_h^2 s^2(b_1) = X_h^2 \frac{\text{MSE}}{\sum X_i^2}$.

5. KNNL Problem 6.2

$$a) \mathbf{X} = \begin{bmatrix} X_{11} & X_{12} & X_{11}^2 \\ X_{21} & X_{22} & X_{21}^2 \\ X_{31} & X_{32} & X_{31}^2 \\ X_{41} & X_{42} & X_{41}^2 \\ X_{51} & X_{52} & X_{51}^2 \end{bmatrix} \quad \boldsymbol{\beta} = \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix}$$

$$b) \mathbf{X} = \begin{bmatrix} 1 & X_{11} & \log X_{12} \\ 1 & X_{21} & \log X_{22} \\ 1 & X_{31} & \log X_{32} \\ 1 & X_{41} & \log X_{42} \\ 1 & X_{51} & \log X_{52} \end{bmatrix} \quad \boldsymbol{\beta} = \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \end{bmatrix}$$

6. (SAS Exercise) Use the **brand preference** data described in KNNL Problem 6.5. Run the linear regression with moisture and sweetness of the product as the explanatory variables and degree of liking as the response variable.

- a. Summarize the regression results by giving the fitted regression equation, the value of R^2 .

The output is shown below. The estimated regression equation is $\hat{Y} = 37.65 + 4.425X_1 + 4.375X_2$. The $R^2 = .9521$.

- b. State the results of the significance test for the null hypothesis that the two regression coefficients for the explanatory variables are *all* zero (give null and alternative hypotheses, test statistic with degrees of freedom, p -value, and a brief conclusion in words).

The p -value of the F-test is $< .0001$. This suggests that the combination of moisture and sweetness is helpful in predicting the brandness liking. This p -value is associated with the null hypothesis that $\beta_1 = \beta_2 = 0$ versus the alternative that at least one of them is not equal to zero. The test statistic is 129.08 and the degrees of freedom are 2 and 13.

- c. Describe the results of the hypothesis tests for the individual regression coefficients (give null and alternative hypotheses, test statistic with degrees of freedom, p -value, and a brief conclusion in words).

The p -values are shown below. Both p -values are less than 0.0001, this implies that we would reject the hypothesis that $\beta_i = 0$ for the alternative $\beta_i \neq 0$. The test statistics are 14.70 and 6.50, the degrees of freedom are 13. The conclusion would be

that either variable **after fitting/adjusting for the other variable** significantly helps predict brandness liking.

- d. Give separate 95% confidence intervals for the regression coefficients of sweetness and moisture. What is the relationship between these confidence intervals and the above hypothesis results?

The 95% CIs are shown below. Because 0 is not included in either confidence interval, this implies that we would reject the hypothesis that $\beta_i = 0$ for the alternative $\beta_i \neq 0$. This can also be seen from the P-values.

Dependent Variable: liking

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	1872.70000	936.35000	129.08	<.0001
Error	13	94.30000	7.25385		
Corrected Total	15	1967.00000			
Root MSE	2.69330	R-Square	0.9521		
Dependent Mean	81.75000	Adj R-Sq	0.9447		
Coeff Var	3.29455				

Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	37.65000	2.99610	12.57	<.0001
moisture	1	4.42500	0.30112	14.70	<.0001
sweetness	1	4.37500	0.67332	6.50	<.0001

Parameter Estimates			
Variable	DF	95% Confidence Limits	
Intercept	1	31.17731	44.12269
moisture	1	3.77447	5.07553
sweetness	1	2.92037	5.82963

NOTE: If you look at the residual plots, to make sure the assumptions are reasonable, there is some evidence of model misfit (a curvilinear relationship between the residuals and predicted values). This may indicate there is an interaction. I fit the model with interaction and the interaction was not significant.
